

Powering IFN- α Research with Ultra-Sensitive Simoa® Technology

Type 1 Interferons (IFNs) are a family of cytokines that play a central role in orchestrating the immune response to viral infections. Among them, IFN- α is the most studied subclass, comprising of 13 subtypes. These IFN- α subtypes are low-abundance yet highly potent proteins. Dysregulated IFN- α levels can adversely affect human health and have been implicated in the pathogenesis of various autoimmune conditions, as well as correlated with more severe disease outcomes. IFN- α holds significant promise as a biomarker for diagnosing, stratifying, and monitoring diseases, as well as a target for therapeutic approaches.

A critical aspect of this promise is the ability to measure IFN- α in blood, which has long been sought after and has only recently become possible with the advent of ultra-sensitive technologies such as the Simoa® digital immunoassay. Since its launch in 2016, Simoa® technology has been actively used in numerous studies related to IFN- α , as evidenced by over 80 peer-reviewed publications included in this brief, which have generated revolutionary insights into IFN- α biology and its clinical applications.

These studies employed various assays for IFN- α measurement, including the catalogued Simoa® IFN- α Advantage and Custom Homebrew Assays measuring either specific IFN- α subtypes or total IFN- α of all subtypes. Quanterix now offers the new Simoa® IFN- α Multi-Subtype (MS) Advantage PLUS (#103836) for ultra-sensitive measurement of total IFN- α .
